# Section 4.5 Solutions and Hints 

by Brent M. Dingle

for the book:<br>Precalculus, Mathematics for Calculus $4^{\text {th }}$ Edition by James Stewart, Lothar Redlin and Saleem Watson.

This section contains quite a few important equations. Depending on your professor you may need to memorize some, all or none of them. They are restated here just for reference. Solved problems follow.

## Exponential Growth Model:

Notice that exponential growth is almost exactly the same as continuously compounded:

| Continuously Compounded Interest | Exponential Growth Model |
| :--- | :--- |
| $A(t)=P e^{r * t}$ | $n(t)=n_{0} e^{r * t}$ |
| where $A(t)=$ amount after $t$ years. | where $n(t)=$ population after $t$ years. |
| $P=$ principal (or initial amount). | $n_{0}=$ initial population size. |
| $r=$ interest rate per year. | $r=$ growth rate per time unit. |
| $t=$ time in years. | $t=$ time in time units. |

So the only real difference is that the growth model does NOT require time to be measured in years.

## Radioactive Decay Model:

$$
m(t)=m_{0} e^{-r t}=m_{0} e^{-\left(\frac{\ln 2}{h}\right) * t}
$$

where $m(t)=$ the mass remaining after time $t$
$m_{0}=$ the initial mass
$t=$ the time
$h=$ the half life
$r=(\ln 2) / h$

## Newton's Cooling Law:

$$
T(t)=T_{s}+D_{0} e^{-k t}
$$

where $T(t)=$ the temperature of an object after time $t$.
$\mathrm{T}_{\mathrm{s}}=$ the temperature of the object's surrounding environment
$\mathrm{D}_{0}=$ the initial temperature difference between the object and its surroundings
$\mathrm{t}=$ time
$\mathrm{k}=$ some positive constant dependent on the type of object.

## pH scale:

The pH of a substance indicates its acidity.
$\mathrm{pH}=7$ means neutral. $\mathrm{pH}<7$ means acidic. $\mathrm{pH}>7$ means basic.
$\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$
where $\left[\mathrm{H}^{+}\right]$is the concentration of hydrogen ions measured in moles per liter $(\mathrm{M})$.

## Richter Scale:

$$
M=\log (I / S)
$$

where $\mathrm{M}=$ magnitude of an earthquake
$\mathrm{I}=$ intensity of the earthquake (measured by amplitude on a seismograph)
$\mathrm{S}=$ standard intensity of a quake, amplitude $=1$ micron $=10^{-4} \mathrm{~cm}$
So the magnitude of a standard earthquake is $\log (1)=0$.

## Decibel Scale:

$$
\beta=10 * \log \left(\mathrm{I} / \mathrm{I}_{0}\right)
$$

where $\beta=$ the intensity level of a sound measured in decibels (dB)
$\mathrm{I}_{0}=10^{-12}$ watts per square meter $\left(\mathrm{W} / \mathrm{m}^{2}\right)$ at a frequency of 1000 hertz. $\mathrm{I}=$ the measured intensity of a sound in $\mathrm{W} / \mathrm{m}^{2}$.
6. The frog population in a small pond grows exponentially. The current population is $\mathbf{8 5}$ frogs and the relative growth rate is $18 \%$ per year.

6 a . Find a function that models the population after $t$ years.

$$
n(t)=n_{0} e^{r^{*} t}
$$

where $n(t)=$ population after $t$ years.
$n_{0}=$ initial population size.
$r=$ growth rate per time unit.
$t=$ time in time units.

So here

$$
\begin{aligned}
& \mathrm{n}_{0}=85 \\
& \mathrm{r}=0.18 \text { per year } \\
& \mathrm{t}=\mathrm{t} \text { years }
\end{aligned}
$$

And we have our model function: $\mathbf{n}(\mathbf{t})=\mathbf{8 5} * \mathbf{e}^{\mathbf{0 . 1 8 *} t}$

## 6b. Find the project frog population in 3 years.

Put 3 in for $t$ into the equation of part (a):

$$
\mathrm{n}(3)=85 * \mathrm{e}^{0.18 * 3}=85 * \mathrm{e}^{0.54} \sim=145.86
$$

So in three years there will be about 145 frogs.

## 6c. Find the number of years required for the frog population to reach 600.

Here we are given $n(t)=800$ and we must find $t$ :

$$
\begin{array}{ll}
800=85 * \mathrm{e}^{0.18 * *} & \text { Isolate the e term by dividing both sides by } 85 \\
800 / 85=\mathrm{e}^{0.18^{*} \mathrm{t}} & \text { Take the natural } \log \text { of both sides } \\
\ln (800 / 85)=\ln \left(\mathrm{e}^{0.18^{*} \mathrm{t}}\right) & \text { Simplify } \\
\ln (800 / 85)=0.18 * \mathrm{t} & \text { Divide both sides by } 0.18 \\
\frac{\ln \left(\frac{800}{85}\right)}{0.18}=t &
\end{array}
$$

Thus $t$ is about 12.455 years.

## 18. Radium 221 has a half life of 30 seconds. How long will it take for $95 \%$ of a sample to decay?

Apply:

$$
\begin{aligned}
& m(t)=m_{0} e^{-r t}=m_{0} e^{-\left(\frac{\ln 2}{h}\right) * t} \\
& \text { where } \\
& m(t)=\text { the mass remaining after time } t \\
& \\
& m_{0}=\text { the initial mass } \\
& t=\text { the time } \\
& h=\text { the half life } \\
& r=(\ln 2) / h
\end{aligned}
$$

We will let our initial amount $\mathrm{m}_{0}=1$
and thus our final amount will be $\mathrm{m}(\mathrm{t})=0.05$ (because 0.95 of it is gone).
$\mathrm{h}=30$ seconds
$\mathrm{t}=$ what we need to solve for (in seconds)

$$
0.05=1 * e^{-\left(\frac{\ln 2) * t}{30}\right)^{2}}
$$

Take ln of both sides

$$
\begin{array}{ll}
\ln (0.05)=\ln \left(e^{-\left(\frac{\ln 2}{30}\right)^{* t}}\right) & \text { Simplify } \\
\ln (0.05)=-\left(\frac{\ln 2}{30}\right) * t \quad & \text { Divide both sides by }-(\ln 2) / 30
\end{array}
$$

$$
-30 * \ln (0.05)
$$
