

Section 5.4

Solutions and Hints

by Brent M. Dingle

for the book:

Precalculus, Mathematics for Calculus 4th Edition
by James Stewart, Lothar Redlin and Saleem Watson.

This entire section is just manipulating stuff into the nice form of:

$$a * \text{function}(k * (x - b))$$

Notice the book leaves off the b assuming you will realize it to be the phase shift as in the previous section (see example 4b in this section)

Also note tangent and cotangent are the only 2 (of the 6) trig functions whose period is π/k . All the others are $2\pi / k$. Thus:

$$\tan(x + \pi) = \tan(x)$$

$$\cot(x + \pi) = \cot(x)$$

$$\csc(x + 2\pi) = \csc(x)$$

$$\sec(x + 2\pi) = \sec x$$

This may come in useful for solving problems in later classes.

36. Find the period and graph: $y = \frac{1}{2} * \tan(\pi * x - \pi)$

Be aware that while it appears k always = the stuff in front of the x , there is a little step you must do to get things into the correct form:

$$\text{We want: } y = a * \tan(k * (x - b))$$

$$\text{We have: } y = \frac{1}{2} * \tan(\pi * x - \pi),$$

So pull out a π and get:

$$y = \frac{1}{2} * \tan(\pi * (x - 1))$$

Thus $k = \pi$ and the period of tangent = π / k , thus the period = $\pi / \pi = \mathbf{1}$

All of these problems work in a similar fashion. PRACTICE DOING THEM !
