6. If a snowball melts so that its surface area decreases at a rate of  $1 \text{ cm}^2$  per minute, find the rate at which the **DIAMETER** decreases when the diameter is 10 cm.

Let  $V$  = volume of a sphere =  $(4/3)\pi r^3$ .

We are given that  $dV/dt = 1$ . We must find  $dr/dt$  so we can find  $dd/dt$ , where  $t$  = time,  $r$  = radius and  $d = 2r$  = diameter.

We begin with the formula for volume and differentiate both sides:

$$\begin{aligned} V &= (4/3)\pi r^3 && \rightarrow d/dt[ V ] = d/dt[ (4/3)\pi r^3 ] \\ &&& \rightarrow dV/dt = (4/3)\pi * 3 * r^2 * dr/dt && \textit{put 1 for dV/dt.} \\ &&& \rightarrow 1 = 4\pi * r^2 * dr/dt && \textit{solve for dr/dt.} \\ &&& \rightarrow \frac{1}{4\pi * r^2} = dr/dt \end{aligned}$$

Given  $d = 2r$ , when  $d = 10$  then  $r = 5$ . So we put 5 in for  $r$ :

$$dr/dt = \frac{1}{4\pi * r^2} = \frac{1}{4\pi * 5^2} = \frac{1}{100\pi}$$

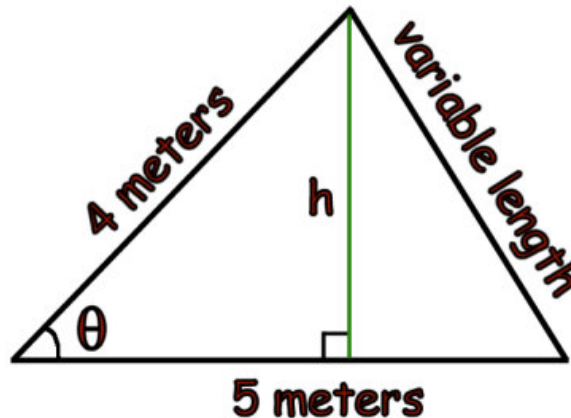

Now we need to find  $dd/dt$ , given that  $dr/dt = \frac{1}{100\pi}$ .

$$\begin{aligned} d &= 2r && \rightarrow d/dt[ d ] = d/dr[ 2r ] \\ &&& \rightarrow dd/dt = 2 * dr/dt \\ &&& \rightarrow dd/dt = \frac{2}{100\pi} \end{aligned}$$

The diameter is decreasing at a rate of  $dd/dt = \frac{1}{50\pi}$  cm/sec when the diameter is 10 cm.

23. Two sides of a triangle are 4 meters and 5 meters in length. The angle between them is increasing at a rate of 0.06 radians per second. Find the rate at which the area of the triangle is increasing when the angle between the sides of fixed length is  $\pi/3$ .

As long as you set this up correctly everything is easy. The way to think is:  
Area is dependent on base and height. One of those needs to be constant and the other needs to be a function of  $\theta$  because we are given  $d\theta/dt$ .

As we have drawn this we see the base of the main triangle will always be 5 m. We also should see that  $\sin(\theta) = h / 4 \rightarrow h = 4 \cdot \sin(\theta)$ . So we have successfully set stuff up so  $h$  is a function of  $\theta$ .

We know: Area =  $A = \frac{1}{2} \cdot (\text{base}) \cdot \text{height}$ .

We have height =  $h = 4 \cdot \sin(\theta)$

So  $dh/dt = d/dt [ 4 \cdot \sin(\theta) ]$

$$\begin{aligned} dh/dt &= 4 \cdot \cos(\theta) \cdot d\theta/dt, && \text{put } 0.06 \text{ in for } d\theta/dt. \\ &= 4 \cdot \cos(\theta) \cdot 0.06 && \text{put } \pi/3 \text{ in for } \theta. \\ &= 4 \cdot \frac{1}{2} \cdot 0.06 \\ &= 0.12 \end{aligned}$$

And now we can use  $dh/dt$  to find  $dA/dt$ :

Area =  $\frac{1}{2} \cdot (\text{base}) \cdot \text{height}$ , *base is constant and = 5.*

$A = \frac{1}{2} \cdot 5 \cdot h$

Thus  $dA/dt = d/dt [ (5/2) \cdot h ]$

$$\begin{aligned} &= (5/2) \cdot dh/dt, && \text{and we found } dh/dt = 0.12. \\ &= 2.5 \cdot 0.12 \\ &= 0.3 \text{ m}^2 / \text{s} \end{aligned}$$

When  $\theta = \pi/3$  the area of the triangle is changing at the rate of **0.3 m<sup>2</sup> / s**.
